Bayes rule

Bayes rule

Joint distribution

$$p(y, \theta|m)$$

$$p(\theta|y,m) = \frac{p(y|\theta,m)p(\theta|m)}{\int p(y|\theta,m)p(\theta|m)d\theta}$$

Expectation

$$E[p(y|\theta,m)]_{p(\theta|m)}$$

Marginal likelihood

$$\int \mathbf{p}(\mathbf{y}, \boldsymbol{\theta} | \mathbf{m}) d\boldsymbol{\theta}$$

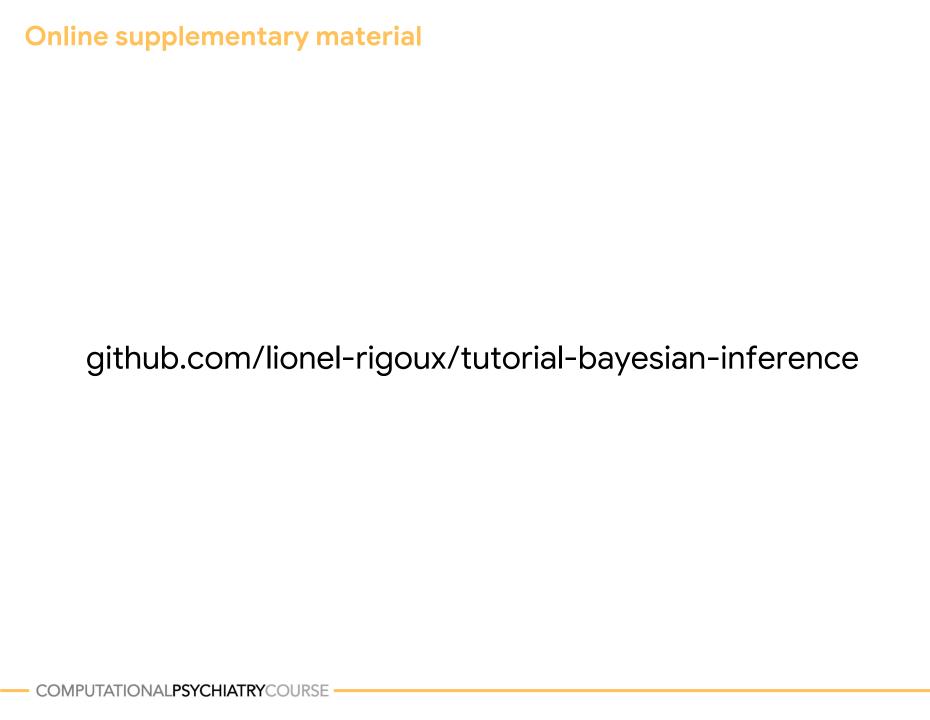

Model evidence

Overview

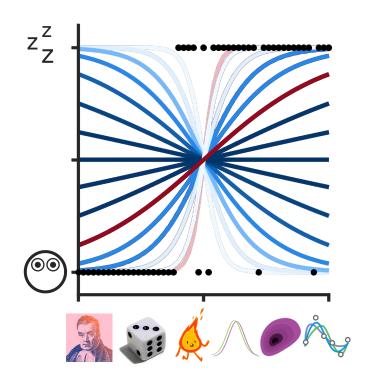

How to compute the posterior belief and the model evidence in practice?

Monte-Carlo (sampling) methods

Variational methods

Example: logistic regression

Model prediction: psychometric (logistic) function

$$p(y_t = 1|u_t, \theta, \beta) = sig(\theta u_t + \beta) = s_t$$

Likelihood

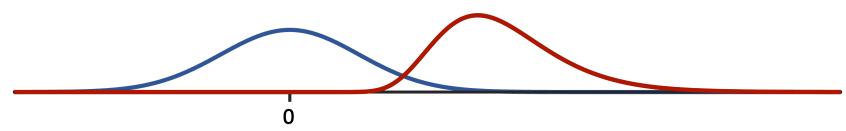

$$y_t \sim \mathcal{B}(s_t)$$

$$p(y|\theta,\beta) = \int s_t^y (1-s_t)^{1-y}$$

Prior

$$\theta \sim \mathcal{N} \big(\mu_\theta, \sigma_\theta^2 \big) \qquad \quad \beta \sim \mathcal{N}(0,0)$$

$$p(\theta) = exp\left(-\frac{1}{2}\frac{(\theta - \mu_{\theta})^2}{\sigma_{\theta}^2}\right)\frac{1}{\sqrt{2\pi\sigma^2}}$$

Example: logistic regression

Joint

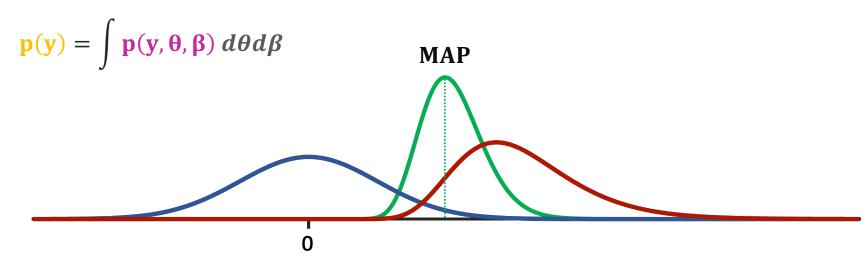

$$p(y, \theta, \beta) \propto \prod s_t^y (1 - s_t)^{1-y} e^{-\frac{(\theta - \mu_\theta)^2}{2\sigma_\theta^2}}$$

$$\log \mathbf{p}(\mathbf{y}, \mathbf{\theta}, \mathbf{\beta}) = \sum_{\mathbf{y}} \mathbf{y} \log \mathbf{s}_{\mathbf{t}} + (\mathbf{1} - \mathbf{y}) \log(\mathbf{1} - \mathbf{s}_{\mathbf{t}}) - \frac{(\mathbf{\theta} - \mathbf{\mu}_{\mathbf{\theta}})^{2}}{2 \sigma_{\mathbf{\theta}}^{2}} + c$$

Posterior

$$p(\theta, \beta|y) \propto p(y, \theta, \beta)$$
 $MAP = \underset{\theta, \beta}{\operatorname{argmax}} p(y, \theta, \beta)$

Model evidence

Sampling (Monte Carlo)

"When one tries continuously, one ends up succeeding. Thus, the more one fails, the greater the chance that it will work."

Les Shadoks

Monte-Carlo methods

Monte-Carlo methods

Expectation (theoretical mean)

$$E[z] = \sum p(z)z = \sum_{z=1}^{6} \frac{1}{6}z = 3.5$$

Variance (theoretical distance to the mean)

$$E[(z-3.5)^2] = \sum p(z)(z-3.5)^2 = 2.9167$$

$$E[z_1 + \cdots + z_n \ge 63] = ?$$
 $n \approx \frac{63}{E[z]} = 18$

Law of Large Numbers

Expectation ≈ Empirical mean

$$E[z] \approx \frac{1}{n} \sum_{i=1}^{n} z_{i} \qquad z_{i} \sim p(z)$$

$$E[f(z)] \approx \frac{1}{n} \sum_{i=1}^{n} f(z_i)$$

Monte-Carlo methods

Model evidence

Arithmetic estimator

$$\mathbf{p}(\mathbf{y}) = \mathbf{E}[\mathbf{p}(\mathbf{y}|\mathbf{\theta})]_{\mathbf{p}(\mathbf{\theta})} \approx \frac{1}{n} \sum_{i} \mathbf{p}(\mathbf{y}|\mathbf{\theta}_i)$$

Harmomic estimator, Gibb's estimator, Annealed importance sampling, etc. Samples from prior

$$\theta_i \sim \mathbf{p}(\boldsymbol{\theta})$$

Posterior moments

Mean

$$\mu = \mathbf{E}[\boldsymbol{\theta}]_{\mathbf{p}(\boldsymbol{\theta}|\mathbf{y})} \approx \frac{1}{n} \sum_{i} \boldsymbol{\theta}_{i}$$

Variance

$$\Sigma = \mathbf{E} \big[(\theta - \mu)^2 \big]_{\mathbf{p}(\theta|\mathbf{y})} \approx \frac{1}{\mathbf{n}} \sum (\theta_i - \widehat{\mu})^2$$

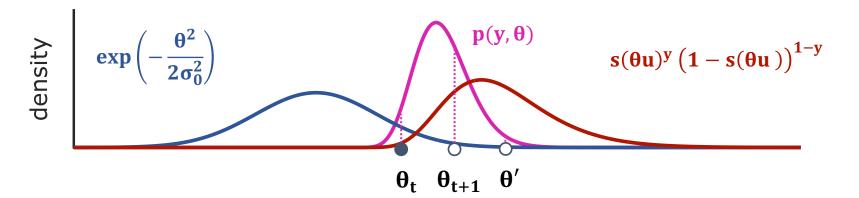

Samples from posterior

$$\theta_i \sim p(\theta|y)$$

Hot and cold game

Metropolis-Hastings algorithm

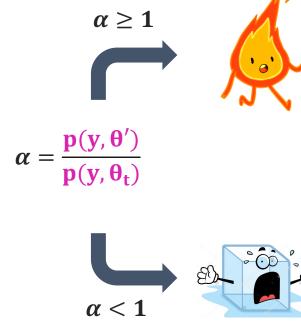

Current state

$$p(y, \theta_t) = p(\theta_t) p(y|\theta_t)$$

Proposal

$$\theta' \! \sim q(\theta|\theta_t)$$

$$p(y, \theta') = p(\theta') p(y|\theta')$$

Jump to proposed value

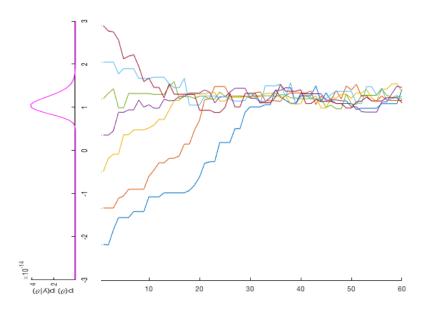

$$\theta_{t+1} = \theta'$$

Draw $x \sim U(0, 1)$

- if $\alpha > x$, jump $\theta_{t+1} = \theta'$
- else, stay in place $\theta_{t+1} = \theta_t$

Did I sample right?

All sampling methods requires some "post-processing" and an extensive diagnostic to ensure the samples are representative.

- 1) Run multiple chains
- 2) Check:
- Convergence (eg. Geweke)
- Mixing (eg. Gelman-Rubin)
- Autocorrelation (decimation)
- Step size (Goldilocks principle)

Multivariate case

Write conditional posteriors

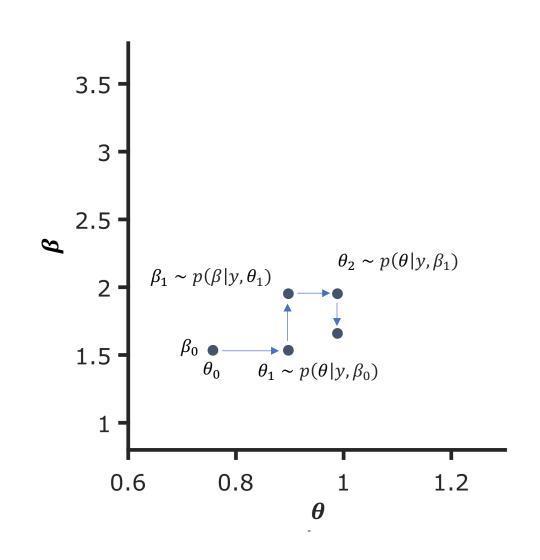

$$p(\theta|y,\beta) = \frac{p(y,\theta,\beta)}{p(y,\beta)}$$

$$p(\beta|y,\theta) = \frac{p(y,\theta,\beta)}{p(y,\theta)}$$

Iterative sampling

$$\theta_t \sim p(\theta|y,\beta_{t-1})$$

$$\beta_t \sim p(\beta|y,\theta_t)$$

Multivariate case

Using the law of large numbers:

Posterior mean

$$E[\theta|y] \approx mean(\theta_t)$$

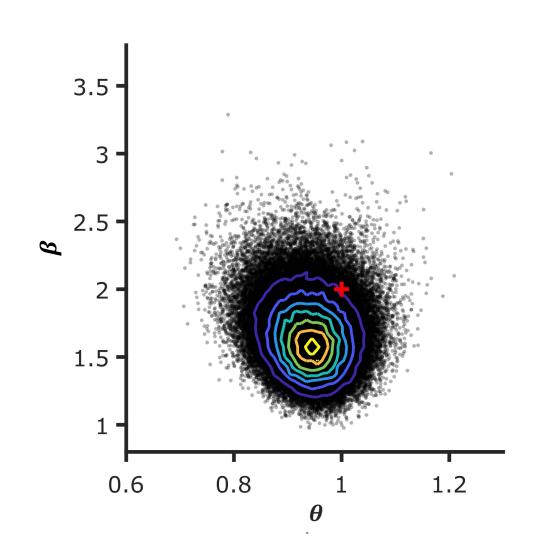

$$E[\beta|y] \approx mean(\beta_t)$$

Posterior variance

$$E\big[(\theta-\overline{\theta})^2\big|y\big]\approx var(\theta_t)$$

$$E\left[\left(\beta - \overline{\beta}\right)^2 \middle| y\right] \approx var(\beta_t)$$

Covariance, etc.

Monte-Carlo inference

Monte-Carlo methods rely on sampling to estimate the posterior and the model evidence.

The Law of Large Numbers guarantees that the sufficient statistics of the samples will converge to the true posterior moments.

Problems

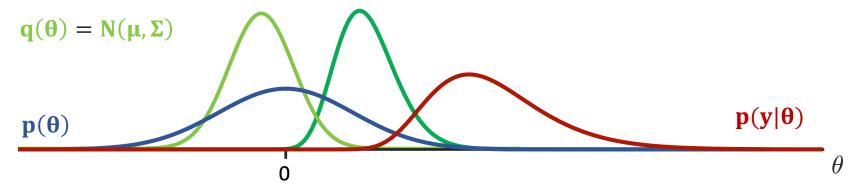

- computationally expensive
- does not scale well with the number of parameters
- hard to tune and diagnose
- no direct measure of model evidence

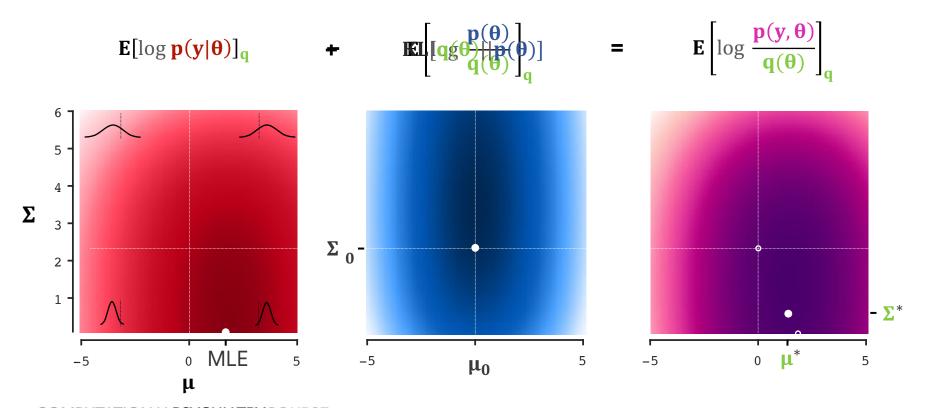

Variational methods

"[Variational inference is the thing you implement while you wait for your Monte-Carlo sampling to finish.]"

David Blei

Approximate posterior

Evidence LOwer Bound

candidate distribution $q(\theta)$

Jensen's inequality

$$\log \mathbf{p}(\mathbf{y}) = \log \int \mathbf{p}(\mathbf{y}, \mathbf{\theta}) \, d\theta$$

$$= \log \int \frac{\mathbf{p}(\mathbf{y}, \mathbf{\theta})}{\mathbf{q}(\mathbf{\theta})} \mathbf{q}(\mathbf{\theta}) d\theta$$

$$= \log E \left[\frac{p(y, \theta)}{q(\theta)} \right]_{q(\theta)}$$

$$= \mathbf{E} \left[\log \frac{\mathbf{p}(\mathbf{y}, \mathbf{\theta})}{\mathbf{q}(\mathbf{\theta})} \right]_{\mathbf{q}(\mathbf{\theta})} + \mathbf{KL}[\mathbf{q}(\mathbf{\theta})||\mathbf{p}(\mathbf{\theta}|\mathbf{y})]$$

ELBO

< p(y)

error

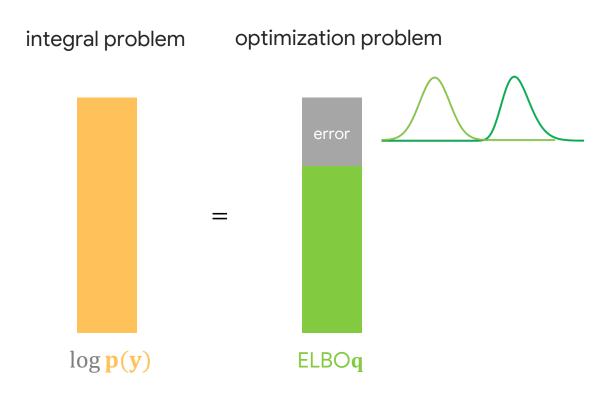

> 0

"it's called the negative variational free energy"

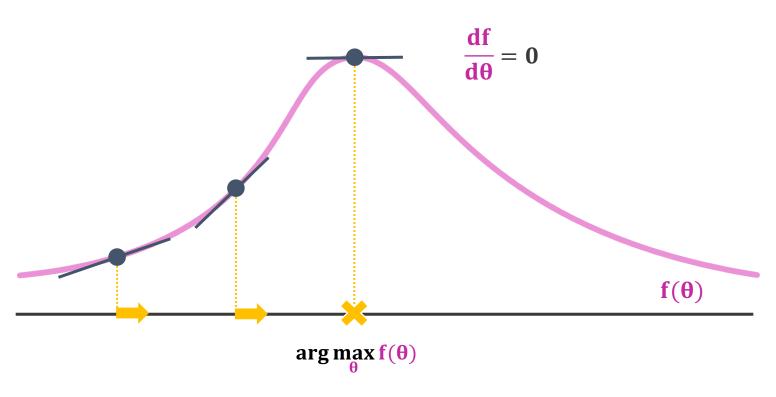

Karl Friston

Evidence LOwer Bound

Finding a maximum

analytical approach: *null derivative* solve conditions for an extremum

numerical approach: gradient ascent follow slope until it gets flat

Maximizing the ELBO: numerical approach

Objective

$$\log \frac{\mathbf{p}(\mathbf{y})}{\approx \max \mathbf{E} \left[\log \frac{\mathbf{p}(\mathbf{y}, \mathbf{\theta})}{\mathbf{q}(\mathbf{\theta})}\right]_{\mathbf{q}(\mathbf{\theta})}$$

Stochastic gradient

VELBO

$$= \mathbf{E} \left[\nabla \log \mathbf{q}(\theta) \left(\log \frac{\mathbf{p}(\mathbf{y}, \theta)}{\mathbf{q}(\theta)} \right) \right]_{\mathbf{q}(\theta)}$$

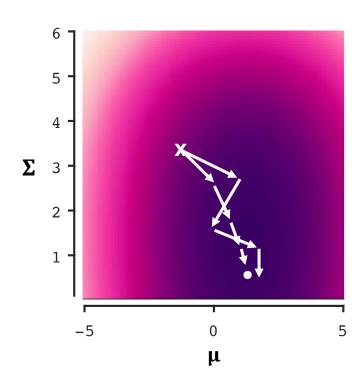

> q derivable, samplable distribution

$$\theta_i^t \sim q^t(\theta) = N(\mu^t, \Sigma^t)$$

MC approximation of expetations

Solution

Gradient ascent

Maximizing the ELBO: analytical approach

Objective

$$\log \frac{\mathbf{p}(\mathbf{y})}{\approx \max \mathbf{E} \left[\log \frac{\mathbf{p}(\mathbf{y}, \mathbf{\theta})}{\mathbf{q}(\mathbf{\theta})}\right]_{\mathbf{q}(\mathbf{\theta})}$$

Variational Laplace

> q exponential family

$$q(\theta) = N(\mu, \Sigma)$$

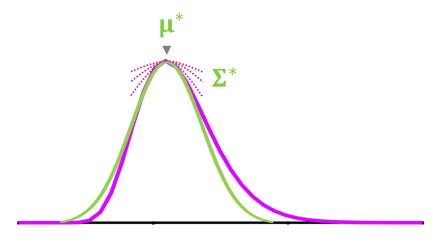

analytical approximation

$$ELBO \approx ELBO_{Laplace}$$

find maximum

$$\frac{d}{dq(\theta)}ELBO_{Laplace} = 0$$

Solution

$$\mu^* = \operatorname{argmax} p(y, \theta) = MAP$$

$$\mathbf{\Sigma}^* = -\left[\frac{\partial^2}{\partial \theta^2}\bigg|_{\mu^*} \log \mathbf{p}(\mathbf{y}, \mathbf{\theta})\right]^{-1}$$

$$\log p(y) \approx \log p(y, \mu^*) + \frac{1}{2} [\log |\Sigma^*| + n_{\theta} \log(2\pi)]$$

Multivariate posterior

Mean field approximation

$$q(\theta, \beta) \approx q(\theta)q(\beta)$$

Variational energy

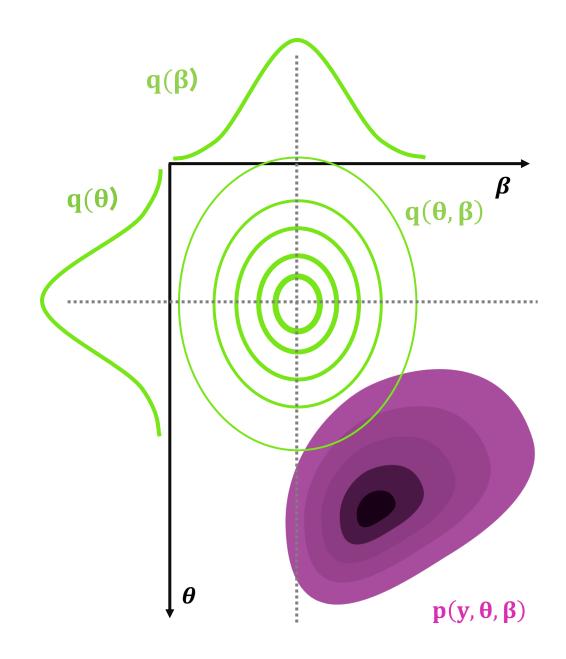

$$I(\theta) = E[\log p(y, \theta, \beta)]_{q(\beta)}$$

$$\approx \log p(y, \theta, \mu_{\beta}) + ...$$

Iterative optimization

$$\mu_i = \operatorname{argmax} I(\theta_i)$$

$$\Sigma_{i} = -\left[\frac{\partial^{2}}{\partial \theta_{i}^{2}} \middle|_{\mu_{i}} I(\theta_{i})\right]^{-1}$$

Multivariate posterior

Mean field approximation

$$q(\theta, \beta) \approx q(\theta)q(\beta)$$

Variational energy

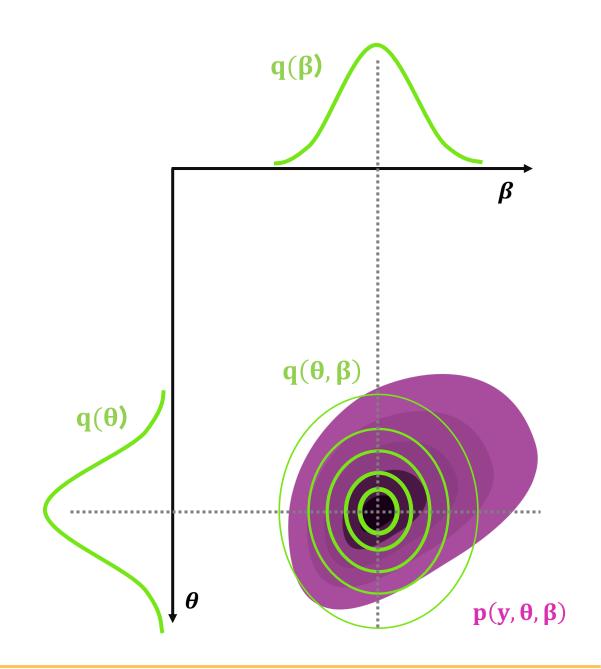

$$I(\theta) = E[\log p(y, \theta, \beta)]_{q(\beta)}$$

$$\approx \log p(y, \theta, \mu_{\beta}) + ...$$

Iterative optimization

$$\mu_i = \operatorname{argmax} I(\theta_i)$$

$$\Sigma_{i} = -\left[\frac{\partial^{2}}{\partial \theta_{i}^{2}} \middle|_{\mu_{i}} I(\theta_{i})\right]^{-1}$$

Variational inference

Approximate posterior with a parametric distribution and find the parametrization which maximizes the ELBO.

This requires multiple approximations (Jensen, shape of the posterior, Laplace & mean-field) to be tractable.

Problems

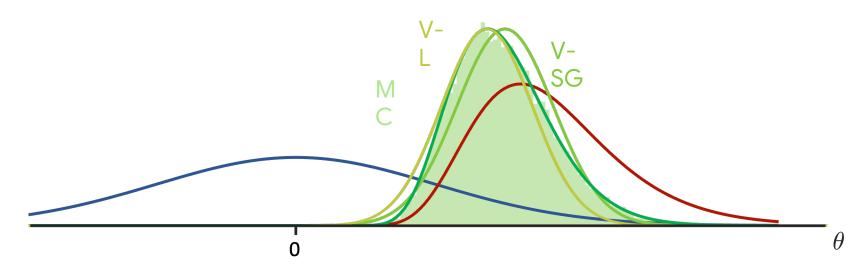

- does not converge to the true posterior
- can get stuck in local optimum

Take home message

Model evidence (normalization factor of the posterior) is in general intractable and calls for numerical methods.

- Sampling methods give a computationally expensive estimation of the true posterior. Good for small models / scarce data.
- ✓ Variational methods are fast & scalable computations of an approximation of the posterior. Good for large models / large data.
